

HTTP Create Post

Description: Write a Python program using the `http.client` module to create a new post via POST request to the JSONPlaceholder API.

Your task is to implement the following function:

1. `create_post(title: str, body: str, user_id: int) -> dict`: This function connects to `'jsonplaceholder.typicode.com'`, sends a POST request to `'/posts'` with JSON body containing title, body, and `userId` fields, `Content-Type: application/json`, reads the response, and returns the parsed JSON.

Input: None.

Output (without unit test): The created post data.

Output (with unit test):

```
Testing create_post ...
connection called with: call('jsonplaceholder.typicode.com')
request called with: call('POST', '/posts', body='{"title": "My Post", "body": "
Post content", "userId": 1}', headers={'Content-Type': 'application/json', 'Content-Length': '55'})
connection closed: call()
test attribute passed: 101 is equal to 101
test attribute passed: My Post is equal to My Post
```
