

HTTP Get Single Post

Description: Write a Python program using the `http.client` module to fetch a single post by ID from the JSONPlaceholder API.

Your task is to implement the following function:

1. `get_post(post_id: int) -> dict`: This function connects to 'jsonplaceholder.typicode.com', sends a GET request to '/posts/{post_id}', reads the response, parses the JSON, closes the connection, and returns the parsed dictionary.

Input: None.

Output (without unit test): The post data as a dictionary.

Output (with unit test):

```
Testing get_post ...
connection called with: call('jsonplaceholder.typicode.com')
request called with: call('GET', '/posts/1')
response read called with: b'{"id": 1, "title": "Test Post", "body": "Test Body", "userId": 1}'
connection closed: call()
test attribute passed: 1 is equal to 1
test attribute passed: Test Post is equal to Test Post
```
