

HTTP POST Form Data

Description: Write a Python program using the socket module that sends a POST request with URL-encoded form data to `httpbin.org`.

Your task is to implement the following function:

1. `post_form_data()` -> str: This function creates a socket, connects to '`httpbin.org`' on port 80, sends a POST request to '/post' with form data '`name=John+Doe&age=30`' and Content-Type: `application/x-www-form-urlencoded`, receives the response, and returns the response body.

Input: None.

Output (without unit test): The response body from the server.

Output (with unit test):

```
Testing post_form_data ...
connect called with: call(('httpbin.org', 80))
send called with: call(b'POST /post HTTP/1.1\r\nHost: httpbin.org\r\nContent-Type: application/x-www-form-urlencoded\r\nContent-Length: 20\r\nConnection: close\r\n\r\nname=John+Doe&age=30')
recv called with: call(4096)
test attribute passed: {"form": {"name": "John Doe", "age": "30"}} is equal to {
"form": {"name": "John Doe", "age": "30"}}
```
