

UDP Echo Server

Background

In this problem, you will implement a UDP echo server that receives a datagram from a client, prints it, and echoes the same payload back to the sender.

Problem Description

Your task is to implement the following:

- A function `handle_once(server_socket)` that performs a single `recvfrom` and replies to the sender with the same data.
- A main flow that creates a UDP socket, binds it to (host, port), and calls `handle_once` exactly one time.

Specifications

- Use `socket.AF_INET` and `socket.SOCK_DGRAM`.
- Read up to 1024 bytes per call.
- Print the received message before echoing it back.

Output (with unit test)

```
Received from ('127.0.0.1', 5050): Ping
test attribute passed: Ping is equal to Ping
```
